Wales Health Board Areas

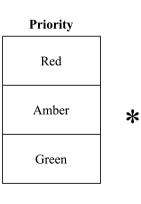

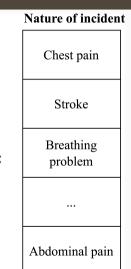

Data

- Daily number of attended incidents:
 - 1 October 2015 31 July 2019
- Disaggregated by:
 - control area
 - health board
 - priority
 - nature of incidents
- 2,142,000 rows observations from 1,530 time series.

Aggregated daily incidents

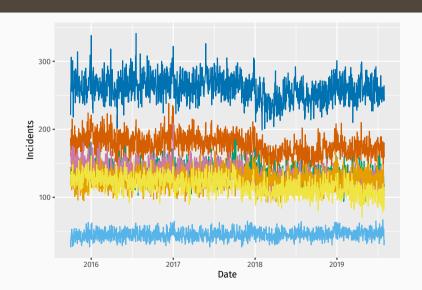

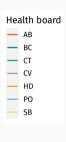

Daily incidents by control area

Data incidents by health board

Data incidents by priority

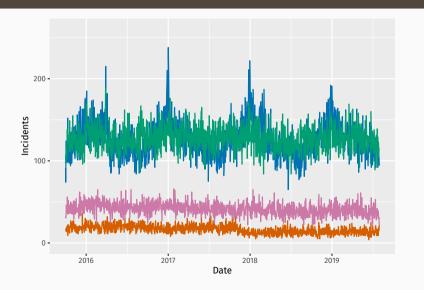

Data incidents by nature of incident

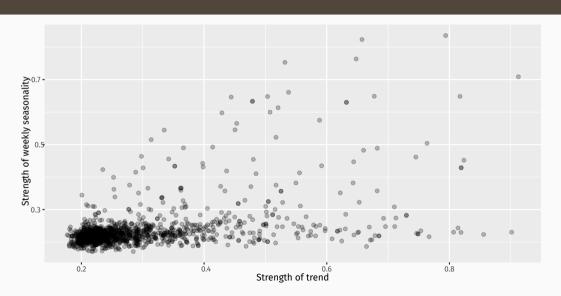

Data incidents by nature of incident

Data features

- **Naïve**: Empirical distribution of past daily attended incidents.
- **ETS**: Exponential Smoothing State Space models.
- **GLM**: Poission Regression with spline trend, day of the week, annual Fourier seasonality, public holidays, school holidays, Christmas Day, New Year's Day.
- **TSGLM**: Poisson Regression with same covariates plus three autoregressive terms.
- **Ensemble**: Mixture distribution of 1–4.

Naïve: Empirical distribution of past daily attended incidents.

$$y_{T+h|T} \sim \text{Empirical}(y_1, \dots, y_T)$$

Naïve: Empirical distribution of past daily attended incidents.

$$y_{T+h|T} \sim \text{Empirical}(y_1, \dots, y_T)$$

ETS: Exponential Smoothing State Space models.

$$y_{T+h|T} \sim \text{Normal}(\hat{y}_{T+h|T}, \hat{\sigma}_{T+h|T}^2)$$

GLM: Poission Regression

$$y_{T+h|T} \sim \text{Poisson}(\hat{y}_{T+h|T})$$

where

$$\hat{y}_{T+h|T} = \exp(\mathbf{x}'_{T+h}\beta)$$

and \mathbf{x}_{T+h} is a vector of covariates including

- spline trend
- day of the week
- annual Fourier seasonality

- public holidays
- school holidays
- Christmas Day
- New Year's Day

TSGLM: Poisson Regression

$$y_{T+h|T} \sim \mathsf{Poisson}(\hat{y}_{T+h|T})$$

where

$$\hat{y}_{T+h|T} = \exp\left(\mathbf{x}'_{T+h}\boldsymbol{\beta} + \sum_{k=1}^{3} \alpha_k \log(y_{T+h-k} + 1)\right)$$

and \mathbf{x}_{T+h} is a vector of covariates including

- spline trend
- day of the week
- annual Fourier seasonality

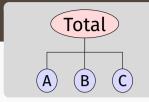

- public holidays
- school holidays
- Christmas Day
- New Year's Day

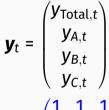

Notation

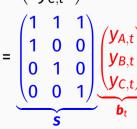

Every collection of time series with linear constraints can be written as

$$y_t = \mathbf{Sb_t}$$

- \mathbf{y}_t = vector of all series at time t
- $y_{Total,t}$ = aggregate of all series at time t.
- $y_{X,t}$ = value of series X at time t.
- **b**_t = vector of most disaggregated series at time t
- S = "summing matrix" containing the linear constraints.

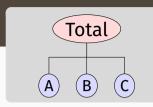

Notation

Every collection of time series with linear constraints can be written as

$$y_t = \mathbf{Sb_t}$$

- \mathbf{y}_t = vector of all series at time t
- $y_{Total,t}$ = aggregate of all series at time t.
- $y_{X,t}$ = value of series X at time t.
- **b**_t = vector of most disaggregated series at time t
- S = "summing matrix" containing the linear constraints.

- Base forecasts: $\hat{\mathbf{y}}_{T+h|T}$
- Reconciled forecasts: $\tilde{y}_{T+h|T} = SG\hat{y}_{T+h|T}$
 - MinT:

$$G = (S'W_h^{-1}S)^{-1}S'W_h^{-1}$$

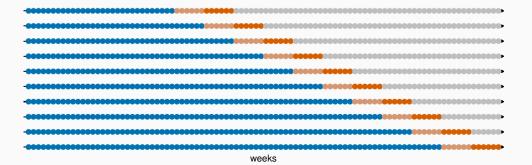

where W_h is
covariance matrix of
base forecast errors.

Nonparametric bootstrap reconciliation

- Fit model to all series and store the residuals as ε_t .
- These should be serially uncorrelated but cross-sectionally correlated.
- Draw iid samples from $\varepsilon_1, \ldots, \varepsilon_T$ with replacement.
- Simulate future sample paths for model using the bootstrapped residuals.
- Reconcile each sample path using MinT.
- Combine the reconciled sample paths to form a mixture distribution at each forecast horizon.

- Ten-fold time series cross-validation
- Forecast horizon of 1–84 days
- Each training set contains an additional 42 days.
- Forecasts at 43–84 days correspond to planning horizon.

$$\mathsf{MASE} = \mathsf{mean}(|q_j|)$$

$$q_j = \frac{e_j}{\frac{1}{T - m} \sum_{t=m+1}^{T} |y_t - y_{t-m}|}$$

- y_t = observation for period t
- e_j = forecast error for forecast horizon j
- T = size of training set
- = m = 7

$$MSSE = mean(q_j^2)$$

$$q_j^2 = \frac{e_j^2}{\frac{1}{T-m} \sum_{t=m+1}^{T} (y_t - y_{t-m})^2}$$

- y_t = observation for period t
- e_j = forecast error for forecast horizon j
- T = size of training set
- = m = 7

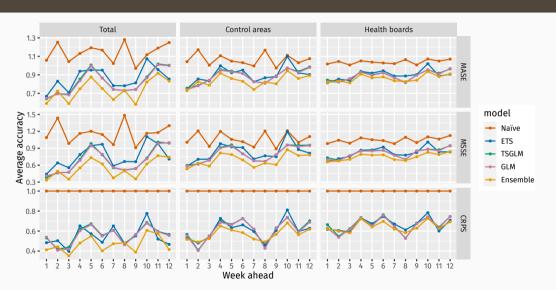

CRPS = mean
$$(p_j)$$

$$p_j = \int_{-\infty}^{\infty} \left(G_j(x) - F_j(x) \right)^2 dx,$$

- $G_i(x)$ = forecast distribution for forecast horizon j
- $F_j(x)$ = true distribution for same period

Forecast accuracy

Forecast accuracy: 43-84 days ahead

Conclusions

- Ensemble mixture distributions give better forecasts than any component methods.
- Forecast reconciliation improves forecast accuracy, even when some component methods are quite poor.
- The ensemble without the Naïve method was worse.
- Forecast reconciliation allows coordinated planning and resource allocation.
